Purpose and Summary of Document

The aim of this document is to provide clinical staff with guidance on the neurotrophic tyrosine receptor kinase (NTRK) gene fusion testing pathway.

The guidance is relevant to all staff involved with the management of adult and paediatric patients (with a diagnosis of any solid tumour) who are eligible to have their tumour tested for this genetic variant.

For those patients whose tumour is subsequently identified to have a NTRK gene fusion and are eligible to receive tropomyosin receptor kinase (TRK)-inhibitors, this guideline summarises the prescribing information and recommended baseline investigations and on-treatment monitoring requirements for these therapies.
**NTRK gene fusion testing request algorithm**

Treating clinician identifies patient as a suitable candidate for NTRK fusion testing (all 4 criteria must be met):
1. Adult or paediatric histological proven diagnosis of malignant solid tumour (of any type)
2. Performance status 0-2
3. Either locally advanced OR metastatic disease OR surgical resection likely to result in severe health problems
4. Patient has no satisfactory treatment options AND has already been treated with all available NHS-funded systemic therapy options for which clinical benefit has been established

Treating clinician/team completes NTRK gene fusion request form and emails to pathology lab storing histology specimen

Pathology lab prepares sample/slides and sends to AWGL (estimated TAT: 5 working days)

AWMGS extract DNA/RNA from slides for gene analysis (estimated TAT: 10 working days/14 calendar days)

AWGL sends report to requesting clinician(s) with phased implementation of upload to healthboards’ WCP (due to complete 2021)

---

**NTRK fusion identified**

To receive a TRK-inhibitor, the following criteria must be met for all patients:
1. Recent baseline imaging performed within last 4 weeks (including CT or MRI brain)
2. Symptomatically stable from any brain metastases (defined as stable neurology and if taking regular steroids, has not required an increase in steroid dose in the 7 days preceding treatment)
3. No previous treatment with a TRK-inhibitor
4. Remains performance status 0-2

Repeat restaging scan (including brain) at 10 weeks to assess response

Continue TRK-inhibitor until disease progression or unacceptable toxicity or patient choice to stop treatment or potentially curative surgery takes place

---

**NTRK fusion not identified**

Patient not eligible for treatment with TRK-inhibitors

Consider:
1. Clinical trials
2. Best supportive care

---

**PLEASE NOTE:**

From Oct 2020, RNA-based NGS (to include NTRK gene analysis) will be routinely available for some tumour types. Although NTRK gene fusion status may be known at this time point, access to TRK-inhibitors must still be within the NICE recommendations and eligibility criteria (see ‘Phased implementation’ section)
Background

It is recognised that malignant tumours can arise due to changes within the DNA of cells. ‘Fusion genes’ are a particular type of genetic alteration in which two unrelated, separate genes join together to form a new hybrid gene with abnormal cellular functions.

The neurotrophic tyrosine kinase (NTRK) gene family is responsible for the normal development and function of both the central and peripheral nervous system (Amatu et al., 2019). The genes NTRK1, NTRK2 and NTRK3, encode for the tropomyosin receptor kinase (TRK) proteins TRKA, TRKB, and TRKC, respectively. These proteins regulate the proliferation, growth and survival of neurons when specific ligands bind to docking sites on their surface. The fusion of the 3’ region of a NTRK gene with a 5’ region of its fusion partner can cause the TRK fusion protein to become expressed and activated, even in the absence of ligand binding; over 80 different partner genes have been identified to date. These fusion proteins can drive the growth of tumour via unregulated cell proliferation and enhanced cell survival via the TRK pathway.

NTRK genes fusions have been identified in a variety of solid tumours, affecting both adults and children. However, the prevalence of these gene fusions varies considerably. They occur very frequently in some rare cancers, for example cases of infantile sarcoma, mammary analogue secretory carcinoma and secretory breast carcinoma, are reported to have a prevalence of >90%, with the ETV6-NTRK3 fusion occurring most frequently in this group (Vaishnavi et al., 2015; Chen & Chi, 2018). Conversely, they are less frequently detected in more common tumour types such as lung or colorectal cancer (see appendix 1; NICE, 2020a). The rarity of NTRK fusions means that we currently do not have a complete understanding of their role in the formation of cancer, which particular fusions types or tumour types are more likely to respond to treatment with inhibition of the TRK pathway, or what the impact of a particular gene fusion may have on prognosis (NICE, 2020b).

NICE has recently made the TRK-inhibitors larotrectinib and entrectinib available as treatment options for adult and paediatric patients with NTRK fusion-positive solid tumours via the Cancer Drugs Fund. These drugs are classed as histology-independent or tumour-agnostic therapies as they target this specific genetic abnormality, regardless of where the cancer originally started within the body. Appendix 2 summaries the current clinical evidence for the efficace of these drugs from the NICE final appraisal documents (NICE, 2020b, c).

NICE states that once a drug is approved for use within the Cancer Drugs Fund, the NHS in Wales must usually provide funding and resources for it
within 2 months of the publication of the final appraisal determination or agreement of a managed access agreement by the NHS in Wales, whichever is the later. However, at present there is no defined clinical pathway for patients with NTRK fusion-positive solid tumours. Clinical pathways are required to ensure equity of access to genetic testing for patients across Wales, regardless of the geographical region in which they reside. There is also limited clinical experience in the use of such histology-independent drugs with a need for formal guidance and staff education.

NTRK testing has only recently been provided within the NHS. There are several techniques available to detect NTRK gene fusions including immunohistochemistry (IHC), fluorescence in-situ hybridization (FISH), reverse transcription polymerase chain reaction (RT-PCR) and next generation sequencing (NGS). NICE recommends the use of nuclei-based assays for NTRK gene fusion testing which must be organised and validated by a recognised genomic laboratory (NICE, 2020a). An initial screening IHC pan-TRK assay followed by a confirmatory FISH or NGS test for suspected cases is not supported given the impact on capacity for IHC in histopathology laboratories associated with this approach and in light of the transition of expanded cancer profiling to genomic laboratories (NICE, 2020b). In addition, the advantage of implementing a RNA NGS-based testing service is the ability to interrogate all clinically actionable genomic variants, and it is a tissue-sparing approach for broad genomic analysis (Hsiao et al., 2019). This is a particularly important consideration given that the number of genetic markers required to guide treatment decisions for many tumour types is increasing and the NHS is committed to implementing genomic testing for cancer patients at the point of diagnosis (NHS, 2019). Furthermore, RNA-based NGS testing is able to determine the fusion partner gene (which is likely to become increasingly clinically relevant as evidence emerges as to the prognostic importance of NTRK gene fusions and characterisation by tumour site) and, very importantly, can detect any secondary mutations (with implications for drug response and resistance).

Since June 2020, NTRK gene fusion testing has been provided as a Welsh Health Specialised Services Committee (WHSSC) commissioned service for all patients in Wales, provided by the All Wales Medical Genomics Service (AWMGS) using FISH. However, the AWMGS is transferring this service to an RNA-based NGS capabilities imminently. It is anticipated that following its validation, the RNA-based NGS technique will be available for clinical use in Wales in the autumn of 2020. FISH analysis will still be available for any patient sample that is unsuitable for RNA-based NGS (estimated at 15-20% of samples).
Phased implementation of NTRK gene fusion testing

The All Wales Genomics-Oncology Group (AWGOG) has determined that given the above challenges, a phased implementation of NTRK gene fusion testing within Wales is required for patients who meet the eligibility criteria for treatment with TRK-inhibitors.

Phase 1

It is proposed that the first short introductory phase will be available from July 2020 for patients in the following groups:

- Tumours with a high prevalence of NTRK gene fusions (>90%) [Infantile fibrosarcoma, congenital mesoblastic nephroma, mammary analogue secretary carcinoma (MASC) of salivary glands, secretory breast cancer]
- Tumours with a NTRK gene fusion prevalence rate of 5-25% [Gastrointestinal stromal tumours (GISTs), thyroid cancers, spitzoid neoplasms]
- Children aged 0-16 years with any solid tumour
- Teenagers aged 16-18 years with any solid tumour
- Young adults 18-25 years with any solid tumour.

Please note: from October 2020, genetic testing on histological specimens for thyroid cancer will be available using both DNA (for single nucleotide genetic variations and insertions/deletions) and RNA-based NGS (for gene arrangements); it is important to note that the results from these panels will be reported separately. If the RNA-based NGS panel is requested for thyroid cancer patients, RET, EGFRvIII and NTRK gene arrangements will be tested for as standard. Whilst the NTRK gene fusion status will be available at an earlier stage in the patient’s treatment pathway, suitable patients will still only be eligible to receive a TRK-inhibitor when there are no satisfactory treatment options available to them (see ‘Eligibility criteria for NTRK gene fusion testing section’).

Phase 2

Phase 2 will commence in October 2020 and will be extended to patients with more common cancer types which have a NTRK gene fusion prevalence rate of 2-5%:
- Lung cancer (including both non-small cell lung cancer (NSCLC) and small cell lung cancer)
- Intrahepatic cholangiocarcinoma
- Brain tumours.

Please note: from October 2020, genetic testing on histological specimens for glioma and locally advanced or metastatic adenocarcinoma of the lung will be available using both DNA (for single nucleotide genetic variations and insertions/deletions) and RNA-based NGS (for gene rearrangements); it is important to note that the results from these panels will be reported separately.

If the RNA-based NGS panel is requested for glioma patients, BRAF gene rearrangements, EGFRvIII structural variants and NTRK gene fusions will be tested for as standard.

For adenocarcinoma of the lung, RNA-based NGS will replace the previous FISH analysis for ALK and ROS1. ALK, ROS1 and NTRK gene fusions will be tested for within the RNA-based NGS panel as standard, along with RET fusions, EGFRvIII structural variants and MET exon 14 skipping variants. The other histological subtypes of lung cancer (e.g. all other types of non-small cell lung cancer and small cell lung cancer) will require NTRK gene fusion testing as per this guideline document.

Whilst the NTRK gene fusion status may be known at an earlier stage in these patients’ treatment pathway, suitable patients will still only be eligible to receive a TRK-inhibitor when there are no satisfactory treatment options available to them (see ‘Eligibility criteria for NTRK gene fusion testing section’).

**Phase 3**

By January 2021, access to NTRK gene fusion testing will be extended to all other patients with a diagnosis of any solid tumour type not cited in phases 1 and 2 (NTRK gene fusion prevalence rate of approximately <2%).
Eligibility criteria for NTRK gene fusion testing

Patients are eligible to have their diagnostic histological specimen screened for NTRK gene fusions if all of the following criteria are met:

1. Adult or paediatric* histological proven diagnosis of solid tumour (of any type^)

2. Performance status 0-2

3. Either locally advanced OR metastatic disease OR surgical resection likely to result in severe health problems

4. Patient has no satisfactory treatment options AND has already been treated with all available NHS-funded systemic therapy options for which a clinical benefit has been established.

[*Entrectinib is recommended in children 12 years and older; larotrectinib does not have any age restrictions]

[^This does not include myeloma, leukaemia or lymphoma]

The purpose of NTRK gene fusion testing is to identify patients who may benefit from treatment with TRK-inhibitors. NICE has recognised that the term ‘no satisfactory treatment options’ may be open to interpretation. The NICE final appraisal documents state that both larotrectinib and entrectinib are positioned as a last-line treatment options where the alternative is best supportive care. This is because clinical benefit has only been established in single-arm trials in a relatively small sample of patients and the effect of treatment with TRK-inhibitors may differ depending on tumour type and other possible gene alterations. Entrectinib is yet to receive its marketing authorisation; as such, the indications for treatment mirror those of larotrectinib.

It is the responsibility of the treating clinician to ensure the above criteria are met and that TRK-inhibitors must not displace any effective therapies. It is recommended that clinical groups within each of the cancer centres review and update their systemic anticancer treatment algorithms to clearly identify when treatment with TRK-inhibitors is indicated within the standard treatment pathway.

The patient is not required to sign a consent form in order proceed with NTRK gene fusion testing. However, the treating clinician should inform the patient as to the rationale for testing, the likelihood of detecting a NTRK gene fusion based on their solid tumour diagnosis and what treatment with TRK-inhibitors entails prior to requesting the test.
**NTRK gene fusion testing request process**

TRK-inhibitors are positioned as last-line treatment options for NTRK fusion-positive solid tumours. As such, the majority of patients will already be known to an oncologist and it is anticipated that in tumour types which do not routinely access RNA-based NGS, requests for NTRK gene fusion testing will be made by the treating clinician rather than via diagnostic MDTs.

NTRK gene fusion testing is performed on the diagnostic histological specimen which requires preparation (slide cutting and tumour assessment) by the local pathology laboratory storing the sample prior to them sending it to the All Wales Medical Genomics Laboratory (AWGL) in Cardiff for analysis. **Requests should therefore not be made directly to the AWGL as samples are not stored here and histopathology services are unavailable in this laboratory.** Due to DNA and RNA degradation over time, the sample should be less than 5 years old; a re-biopsy may necessary to acquire fresh tissue if the diagnostic sample is older than this.

There are likely to be local considerations across the various regions of Wales in terms of the test requesting pathway. However all requests should be made using the appropriate AWGL request form which is available at: [http://www.medicalgenomicswales.co.uk](http://www.medicalgenomicswales.co.uk).

The oncologist should complete the patient demographic information and enter their own name and email address in the appropriate sections. In order to reduce turnaround times, it is recommended that the form is then emailed to the local pathology laboratory storing the diagnostic specimen which is to be tested. The majority of laboratories now have generic emails addresses, the accounts for which are checked on a daily basis (see table 1). If a generic address is not available, the request should be sent to a named individual at the local pathology laboratory who knows to expect the request and initiate the required sample preparation thus avoiding unnecessary delays.

Table 1: Generic email address details for health boards

**Please note: It is not necessary to ask the patient to sign the test request form to indicate their consent for the test to be undertaken. This is a standard pre-printed AWGL form.**

The pathology laboratory should prepare the sample in line with the AWGL recommendations (see ‘Histopathological sample preparation requirements’ section) according to the current phase of **NTRK** testing at the time of the request being made. The pathology laboratory should complete the request form and send a paper copy of the form with the prepared slides directly to the AWGL within a 5 working day turnaround time. It should be noted that historical specimens may be stored off-site and in such circumstances, the turnaround time for this stage may be longer.

Upon receipt of the sample at AWGL, the result will be available within an estimated 10 working days (or 14 calendar days) turnaround time. Hard copies of the report will be emailed to the requesting clinician(s) (as listed on the request form) as a PDF file although it is the aim that by 2021 these will be available on the healthboards’ Welsh Clinical Portal systems using a phased implementation approach.
The contact details for the AWGL are as follows:
All Wales Genetics Laboratory
Institute of Medical Genetics
University Hospital of Wales
Heath Park
Cardiff CF14 4XW
Telephone: 02921845347
Email address: Admin.Genetics.cav@wales.nhs.uk
Website: http://www.medicalgenomicswales.co.uk
Opening hours: Monday – Friday 8.30am – 5:00pm

**NTRK gene fusion testing for privately funding patients**

*NTRK* gene fusion testing is a WHSSC-funded service. However it is also available for privately funding patients. Please contact the AWGL directly for further details.
**Histopathological sample preparation requirements**

The local pathology laboratory housing the diagnostic specimen should prepare the sample as follows before sending the slides to AWGL with the request form:

<table>
<thead>
<tr>
<th>Phase 1</th>
<th>1 x H&amp;E stained slide with area of highest neoplastic cell content CLEARLY circled</th>
</tr>
</thead>
<tbody>
<tr>
<td>(July 2020 – October 2020)</td>
<td>6 x 3-4 µm sections (singly mounted) on charged/adhesion slides for FISH testing</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Phase 2 and 3</th>
<th>1 x H&amp;E stained slide with area of highest neoplastic cell content CLEARLY circled</th>
</tr>
</thead>
<tbody>
<tr>
<td>(October 2020 onwards)</td>
<td>5x10µM air dried unstained sections mounted on slides.</td>
</tr>
<tr>
<td></td>
<td>Note: slides for RNA ideally prepared in an RNase-free environment</td>
</tr>
<tr>
<td></td>
<td>6x 3-4 µm sections (singly mounted) on charged/adhesion slides for FISH testing</td>
</tr>
<tr>
<td></td>
<td>Note: for salvage FISH testing in the event that RNA-based NGS cannot be performed or is unsuccessful</td>
</tr>
</tbody>
</table>

Please note that AWGL will be returning all unused slides to the referring pathology laboratory to file as part of the archive.
Interpreting a *NTRK* gene fusion test result

*NTRK* fusions are typically mutually exclusive of *KRAS*, *NRAS*, *BRAF*, *MAP2K1*, *EGFR*, *ALK*, *RET*, *ROS1*, *KIT*, *PDGFRA* and other *MAPK* driver mutations/fusions. The most common *NTRK* partner genes are *TPM3*, *LMNA*, *TPR*, *EML4*, and *SQSTM1*. The fusions will be reported in line with Human Genome Variation Society (HGVS) nomenclature guidelines, (HGVS, 2020).

When a *NTRK* gene fusion test is reported in isolation, the following outcomes are possible (the exact wording may differ on a case-by-case basis if clinically appropriate):

1. **Actionable *NTRK* gene fusion identified**

The diagnostic comment will describe the type of fusion identified: *e.g. TPM-NTRK1 gene fusion detected (#HGVS nomenclature#). No gene fusions involving NTRK2 or NTRK3 detected.*

Therapeutic comment: *This patient may respond to TRK inhibitors. In patients with tumours harbouring an NTRK gene fusion, treatment with a TRK inhibitor has been shown to be associated with high objective response rates (Drilon, A. et al. (2018) The New Eng J of Med 378,8: 731-739; Doebele, R.C. et al. (2020) Lancet Oncology 21 (2): 271-282).*

If a *NTRK* gene fusion is identified, the patient should be considered for treatment with TRK-inhibitors (see ‘Eligibility criteria for treatment with TRK-inhibitors’ section) as long as they have a performance status of 0-2, with either locally advanced OR metastatic disease OR surgical resection likely to result in severe health problems, and they have no satisfactory treatment options AND has already been treated with all available NHS-funded systemic therapy options for which a clinical benefit has been established.

2. **No actionable *NTRK* gene fusion detected**

Diagnostic comment: *No gene fusions detected in NTRK 1, NTRK2 or NTRK3 detected*

Therapeutic comment: *This patient has a reduced likelihood of response to treatment with TRK inhibitors*

If a *NTRK* gene fusion is not identified, the patient is not eligible for treatment with TRK-inhibitors. The treating clinician should consider whether the patient is a suitable candidate for any clinical trials or offer best supportive care.
3. Failed report: RNA of insufficient quality following FFPE extraction for NGS analysis

Diagnostic comment: NGS analysis failed; insufficient quality RNA for NGS analysis
Conclusive comment: FISH analysis for NTRK 1, NTRK2 and NTRK3 has been initiated

FISH analysis will be initiated if sufficient material has been provided (as per request form) and results will be reported within 14 calendar days of the date of this failed report. If insufficient material has been provided for the FISH salvage pathway to be initiated, the report will note that additional material will be required in order to proceed with any further analysis. This may require a dialogue between the requesting clinician, local pathology laboratory and AWGL to ascertain whether a further biopsy is clinically indicated.

4. Failed report: RNA of insufficient quantity following FFPE extraction for NGS analysis

Diagnostic comment: Insufficient RNA for NGS analysis
Conclusive comment: FISH analysis for NTRK 1, NTRK2 and NTRK3 has been initiated

FISH analysis will be initiated if sufficient material has been provided (as per request form) and results will be reported within 14 calendar days of the date of this failed report. If insufficient material has been provided for the FISH salvage pathway to be initiated, the report will note that additional material will be required in order to proceed with any further analysis. This may require a dialogue between the requesting clinician, local pathology laboratory and AWGL to ascertain whether a further biopsy is clinically indicated.

If NTRK gene fusions are tested for as part of a RNA-based NGS panel, the diagnostic and therapeutic comments will mirror those given above for each of the gene fusions tested e.g. ETV6-NTRK3 gene fusion detected (#HGVS nomenclature#). No gene fusions involving ALK, RET, ROS1, NTRK1 or 2 detected. The EGFRvIII structural variant and MET exon 14 skipping variant were not detected.

Whilst the NTRK gene fusion status may be available at an earlier stage in these patients’ treatment pathway, suitable patients will still only be eligible to receive a TRK-inhibitor when there are no satisfactory treatment options available to them (see ‘Eligibility criteria for NTRK gene fusion testing section’).

Appendix 5 contains examples of NTRK gene fusion reports.
Eligibility criteria for treatment with TRK-inhibitors

If a \textit{NTRK} gene fusion is identified, the patient must meet \textbf{all} of the following 4 criteria in order to receive treatment with a TRK-inhibitor:

1. Recent baseline imaging performed of disease within last 4 weeks (including CT or MRI brain)
2. Symptomatically stable from any brain metastases (defined as stable neurology and if taking regular steroids, patient has not required an increase in steroid dose in the 7 days preceding treatment)*
3. No previous treatment with a TRK-inhibitor

[*Based on inclusion criteria in the \textit{NTRK} trials]

The patient should provide written consent prior to cycle 1 of treatment.

\textbf{TRK-inhibitor prescribing information}

The choice of TRK-inhibitor (i.e. larotrectinib or entrectinib) should be made by the treating clinician on a case-by-case basis, taking into account patient specific factors (e.g. comorbidities, acceptability of potential toxicities) and clinical experience.

Detailed prescribing information for larotrectinib and entrectinib is provided in appendix 3 and 4, respectively.

Treatment with TRK-inhibitors should continue until disease progression, or unacceptable toxicity, or patient chooses to stop treatment, or potentially curative surgery takes place.

No treatment breaks of more than 6 weeks beyond the expected cycle length are allowed (to allow any toxicity of current therapy to settle or intercurrent comorbidities to improve).
Baseline investigations and on-treatment monitoring for TRK-inhibitors

Table 2 summarises the required baseline investigations and on-treatment monitoring for patients receiving TRK-inhibitors.

Appendix 2  Summary of clinical trials using TRK-inhibitors

1.1 Larotrectinib

NICE approved larotrectinib based on the pooled analysis of 102 patients from three trials (NICE, 2020a). The data was evaluated in two groups; the first included 93 patients with 14 tumour sites whilst the second included 9 patients with primary CNS tumours.

- NAVIGATE contributed 62 patients to the pooled analysis and is an ongoing basket trial for aged 12 years or older with NTRK gene fusion who had received prior therapy or, in the opinion of the investigator, would be unlikely to derive clinically meaningful benefit from standard of care therapy.
- SCOUT is an ongoing trial which recruits paediatric patients with locally advanced or metastatic solid tumour or primary CNS tumours (32 patients included in pooled analysis).
- LOXO-TRK-14001 a dose-finding study in patients with solid tumours harbouring NTRK fusion from which the data relating to 8 patients was included.

The primary outcome measure for the 2 larger trials was overall response rate, which in the pooled analysis was reported to be 72% across multiple tumour types, ranging from 0% to more than 95%. NICE noted that due to the immaturity of the data, the long-term benefit of larotrectinib on survival cannot be reliably estimated. The reported median overall survival was variable; for common cancer types (including non-small cell lung cancer and colorectal cancer) ranged from 2.3 to 17 months whilst for thyroid carcinoma, GIST and certain soft tissue sarcomas, median overall survival was not reached. Median progression free survival was generally less than 12 months across included tumour types (NICE, 2020a). Pronounced variability in the percentage of patients experiencing serious adverse events (SAEs) was evident, ranging from less than 10%, to 100% in the included trials. Treatment-related SAEs were reported in patients with all evaluated tumour types.

1.2 Entrectinib

A pooled analysis of data from 66 patients (adults and children) recruited to four clinical trials was initially presented to NICE (NICE, 2020d):

- STARTRK-2 is an ongoing phase 2 basket trial in adults with advanced or metastatic solid tumours with NTRK, ROS1 or ALK gene fusions; 51 patients were included in the pooled analysis
- ALKA is an ongoing phase I trial that contributed 1 adult patient
- STARTRK-1 is an ongoing phase I trial which contributed 2 adult patients
- Data relating to children was collected from the STARTRK-NG trial, a dose escalation and expansion study in patients aged 2 to 22 years.

Exact results were not reported by NICE and although a clinically relevant overall response rate across 13 tumour types was demonstrated, median follow-up was short and survival data were immature.

The following article provides further information:

### Appendix 3  Prescribing information for larotrectinib

<table>
<thead>
<tr>
<th>Dosage:</th>
<th>Larotrectinib (ADULTS)</th>
<th>Initiate at 100mg po twice daily continuous therapy</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Larotrectinib (PAEDIATRICS)</td>
<td>Initiate at 100mg/m² po twice daily continuous therapy. Maximum of 100 mg per dose.</td>
</tr>
<tr>
<td>The starting dose of larotrectinib should be reduced by 50% in patients with moderate (Child-Pugh B) to severe (Child-Pugh C) hepatic impairment. No dose adjustment is recommended for patients with mild hepatic impairment (Child-Pugh A).</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Co-administration with strong CYP3A4 inhibitors: If co-administration with a strong CYP3A4 inhibitor is necessary, the larotrectinib dose should be reduced by 50%. After the inhibitor has been discontinued for 3 to 5 elimination half-lives, larotrectinib should be resumed at the dose taken prior to initiating the CYP3A4 inhibitor.</td>

<tr>
<td>If a dose is missed, the patient should not take two doses at the same time to make up for a missed dose. Patients should take the next dose at the next scheduled time. If the patient vomits after taking a dose, the patient should not take an additional dose to make up for vomiting.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Larotrectinib has a moderate influence on the ability to drive and use machines. Dizziness and fatigue have been reported in patients receiving larotrectinib, mostly Grade 1 and 2 during the first 3 months of treatment. This may influence the ability to drive and use machines during this time period and patients should be advised not to do so until they are reasonably certain larotrectinib does not affect them adversely.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Review clinic:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>By Consultant / Registrar / appropriately trained healthcare professional.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Clinical review 2 weeks after starting, then every 4 weeks.
Continue until disease progression, or unacceptable toxicity, or patient chooses to stop treatment, or potentially curative surgery takes place.

**Anti-emetics:**
Nausea & vomiting are very common – consider co-prescribing an anti-emetic.

**Regular investigations**
- **FBC / U&Es / LFTs**
  - Monitor at baseline and every 2 weeks during the first month of treatment, then monthly thereafter *(based on FDA SPC)*
- **Serum lipase / amylase**
  - Monitor at baseline and as clinically indicated

For all Grade 2 adverse reactions, continued dosing may be appropriate however close monitoring to ensure no worsening of the toxicity is advised.

For Grade 3 or 4 adverse reactions:
- Larotrectinib should be withheld until the adverse reaction resolves or improves to baseline or Grade 1. Resume at the next dose modification if resolution occurs within 4 weeks.
- Larotrectinib should be permanently discontinued if an adverse reaction does not resolve within 4 weeks.

### Recommended dose modifications for adverse reactions

<table>
<thead>
<tr>
<th>Dose modification</th>
<th>Adult and paediatric patients with body surface area of at least 1.0 m²</th>
<th>Paediatric patients with body surface area less than 1.0 m²</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>First</strong></td>
<td>75 mg twice daily</td>
<td>75 mg/m² twice daily</td>
</tr>
<tr>
<td><strong>Second</strong></td>
<td>50 mg twice daily</td>
<td>50 mg/m² twice daily</td>
</tr>
<tr>
<td><strong>Third</strong></td>
<td>100 mg once daily</td>
<td>25 mg/m² twice daily</td>
</tr>
</tbody>
</table>

Larotrectinib should be permanently discontinued in patients who are unable to tolerate treatment after three dose modifications.
The most common adverse drug reactions (≥ 20%) in clinical trials of larotrectinib in order of decreasing frequency were fatigue (32%), increased ALT (31%), dizziness (30%), increased AST (29%), constipation (29%), nausea (26%), anaemia (24%), and vomiting (20%).

The majority of adverse reactions were Grade 1 or 2.

Grade 4 adverse reactions were neutrophil count decreased (1.6%) and ALT increased (< 1%).

Grade 3 adverse reactions were anaemia, weight increased, fatigue, increased AST, dizziness, paraesthesia, nausea, myalgia, and leukocyte count decreased. All reported Grade 3 adverse reactions occurred in less than 5% of patients, with the exception of anaemia (7%).

Permanent discontinuation of larotrectinib for treatment emergent adverse reactions, regardless of attribution occurred in 3% of patients (one case each of ALT increase, AST increase, intestinal perforation, jaundice, small intestinal obstruction). The majority of adverse reactions leading to dose reduction occurred in the first three months of treatment.

**Neurological toxicity:**

Neurologic reactions including dizziness, gait disturbance and paraesthesia were reported in patients receiving larotrectinib.

For the majority of neurologic reactions, onset occurred within the first three months of treatment.

Withholding, reducing, or discontinuing larotrectinib dosing should be considered, depending on the severity and persistence of these symptoms.

**Haematological toxicity:**

Grade 3/4 anaemia, neutropenia & leukopenia have been reported.

**Serum lipase / amylase**

Raised serum lipase and amylase have been noted in clinical trials and consideration to pancreatitis is needed.

**Contraception:**

Verify the pregnancy status of females of reproductive potential prior to initiating. Women of childbearing potential must use highly effective contraception while taking larotrectinib and for at least one month after stopping treatment. Males of reproductive potential with a non-pregnant woman partner of child bearing potential should be advised to use highly effective contraception during treatment with larotrectinib and for at least one month after the final dose.
### Renal impairment:

No dose adjustment is required for patients with renal impairment.

### Hepatic impairment:

The starting dose of larotrectinib should be reduced by 50% in patients with moderate (Child-Pugh B) to severe (Child-Pugh C) hepatic impairment. No dose adjustment is recommended for patients with mild hepatic impairment (Child-Pugh A).

Monitor liver tests including ALT and AST every 2 weeks during the first month of treatment, then monthly thereafter and as clinically indicated. **(based on FDA SPC)**

ALT and AST increase were reported in patients receiving larotrectinib. The majority occurred in the first 3 months of treatment. Patients with Grade 2 ALT and/or AST increases, should be followed with serial laboratory evaluations every one to two weeks after the observation of Grade 2 toxicity until resolved to establish whether a dose interruption or reduction is required.

In patients who develop transaminase elevations, either withhold, or permanently discontinue larotrectinib based on severity. If withheld, the larotrectinib dose should be modified when resumed.

### Interactions:

Larotrectinib is a substrate of cytochrome P450 (CYP) 3A, P-glycoprotein (P-gp) and breast cancer resistance protein (BCRP).

Co-administration of larotrectinib with strong CYP3A inhibitors, P-gp and BCRP inhibitors (e.g. atazanavir, clarithromycin, indinavir, itraconazole, ketoconazole, nefazodone, nelfinavir, ritonavir, saquinavir, telithromycin, troleandomycin, voriconazole or grapefruit) may increase larotrectinib plasma concentrations. If co-administration with a strong CYP3A4 inhibitor is necessary, consult the Summary of Product Characteristics (SPC) for dose reduction advice.

Co-administration of larotrectinib with strong or moderate CYP3A and P-gp inducers (e.g. carbamazepine, phenobarbital, phenytoin, rifabutin, rifampin, or St. John's Wort) may decrease larotrectinib plasma concentrations and should be avoided.

If concomitant use of larotrectinib with CYP3A substrates with narrow therapeutic range is required (e.g. alfentanil, ciclosporin, dihydroergotamine, ergotamine, fentanyl, pimozide, quinidine, sirolimus, or tacrolimus), a dose reduction of the CYP3A substrate may be required due to adverse reactions.
Appendix 4  Prescribing information for entrectinib

<table>
<thead>
<tr>
<th>Drugs/Dosage:</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Entrectinib (ADULTS)</strong></td>
<td>initiate at 600mg po once daily continuous therapy</td>
</tr>
</tbody>
</table>
| **Entrectinib (PAEDIATRICS > 12 years old)** | Initiate at:  
BSA > 1.50m²: 600mg po once daily;  
BSA 1.11 to 1.50m²: 500mg po once daily;  
BSA 0.91 to 1.10m²: 400mg po once daily. |

**Moderate and strong CYP3A Inhibitors:**

Adults and paediatric patients 12 years and older with BSA>1.50 m².

Avoid co-administration of entrectinib with moderate or strong CYP3A inhibitors. If co-administration cannot be avoided, reduce the dose as follows:

- Moderate CYP3A Inhibitors: 200 mg orally once daily
- Strong CYP3A Inhibitors: 100 mg orally once daily

After discontinuation of a strong or moderate CYP3A inhibitor for 3 to 5 elimination half-lives, resume the entrectinib dose that was taken prior to initiating the CYP3A inhibitor.

**DISCUSS WITH PHARMACY**

Available as: Capsules: 100 mg and 200 mg

**Administration:**

Swallow capsules whole. Do not open, crush, chew, or dissolve the contents of the capsule.

If a patient misses a dose, instruct patients to make up that dose unless the next dose is due within 12 hours.

If a patient vomits immediately after taking a dose, instruct patients to repeat that dose.

**Review clinic:**

By Consultant / Registrar / appropriately trained healthcare professional.
Clinical review 2 weeks after starting, then every 4 weeks.

Continue TRK-inhibitor until disease progression, or unacceptable toxicity, or patient chooses to stop treatment, or potentially curative surgery takes place.

**Anti-emetics:**
Nausea & vomiting are very common – consider co-prescribing an anti-emetics.

**Regular investigations:**
- **FBC / U&Es / LFTs / serum urate**
  Monitor at baseline and then every 2 weeks during the first month of treatment, then monthly thereafter *(based on FDA SPC)*
- **Serum lipase / amylase**
  Monitor at baseline and as clinically indicated.
- **Left ventricular ejection fraction**
  Consider assessment of LVEF before initiating treatment.
- **ECG**
  Consider assessment of QT interval in those at risk of QT prolongation.

**Dose modifications:**
Recommended dose reductions for adverse reactions

<table>
<thead>
<tr>
<th>Action</th>
<th>Adults and Paediatric Patients 12 Years and Older with BSA Greater than 1.50 m² (Orally once daily)</th>
<th>Paediatric Patients 12 Years and Older with BSA of 1.11 to 1.50 m² (Orally once daily)</th>
<th>Paediatric Patients 12 Years and Older with BSA of 0.91 to 1.10 m² (Orally once daily)</th>
</tr>
</thead>

<tr>
<td>Second dose reduction*</td>
<td>200mg</td>
<td>200mg</td>
<td>200mg</td>
</tr>
</tbody>
</table>

*For a subsequent modification, permanently discontinue entrectinib in patients who are unable to tolerate after two dose reductions.

Dosage modifications for specific adverse reactions: see below.
Main toxicities:

- Tiredness, constipation, change in taste, swelling, dizziness, diarrhoea, nausea, abnormal touch sensation, shortness of breath, muscle pain, confusion, mental status changes, memory problems, and hallucinations, weight gain, cough, vomiting, fever, joint pain, vision changes.

Cardiac toxicity:

- Congestive heart failure (CHF):
  - Assess left ventricular ejection fraction prior to initiation of entrectinib in patients with symptoms or known risk factors for CHF. Monitor patients for clinical signs and symptoms of CHF.
  - For patients with myocarditis, with or without a decreased ejection fraction, MRI or cardiac biopsy may be required to make the diagnosis. For new onset or worsening CHF, withhold entrectinib, reassess LVEF and institute appropriate medical management.
  - Reduce dose or permanently discontinue based on severity of CHF or worsening LVEF.

</tr>
</tbody>
</table>
| Grade 3 | • Withhold entrectinib until recovery to less than or equal to Grade 1 or to baseline.  
• Resume at same dose if resolution occurs within 4 weeks.  
• Permanently discontinue if adverse reaction does not resolve within 4 weeks.  
• Resume at a reduced dose for recurrent Grade 3 events that resolve within 4 weeks. |
| Grade 4 | • Withhold entrectinib until recovery to less than or equal to Grade 1 or to baseline.  
• Resume at reduced dose if resolution occurs within 4 weeks.  
• Permanently discontinue if adverse reaction does not resolve within 4 weeks.  
• Permanently discontinue for recurrent Grade 4 events. |
| ALT or AST >3 times ULN with concurrent total bilirubin > 1.5 times ULN (in the absence of cholestasis or haemolysis). | • Permanently discontinue entrectinib. |

**Hyperuricaemia:**
Assess serum uric acid levels prior to initiation and periodically during treatment with entrectinib. Monitor patients for signs and symptoms of hyperuricemia. Initiate treatment with urate lowering medications as clinically indicated and withhold entrectinib for signs and symptoms of hyperuricemia. Resume at same or reduced dose upon improvement based on severity.
### Symptomatic or Grade 4
- Initiate urate-lowering medication.
- Withhold entrectinib until improvement of signs or symptoms.
- Resume entrectinib at same or reduced dose.

---

### Visual disturbances:
Withhold for new visual changes or changes that interfere with activities of daily living until improvement or stabilization. Conduct an ophthalmological evaluation as appropriate. Resume at same or reduced dose upon improvement or stabilization.

<table>
<thead>
<tr>
<th>Severity</th>
<th>Dosage Modification</th>
</tr>

<tr>
<td></td>
<td></td>
<td>• Resume at the same dose or reduced dose, as clinically appropriate.</td>
</tr>
</tbody>
</table>

---

### Other clinically relevant

---
| adverse reactions: | Grade 3 or 4 | • Withhold entrectinib until adverse reaction resolves or improves to recovery or improvement to Grade 1 or baseline.  
• Resume at the same or reduced dose, if resolution occurs within 4 weeks.  
• Permanently discontinue if adverse reaction does not resolve within 4 weeks.  
• Permanently discontinue for recurrent Grade 4 events. |
| Skeletal fractures: | Entrectinib increases the risk of fractures. Promptly evaluate patients with signs or symptoms of fractures. |
| Serum lipase / amylase | Raised serum lipase and amylase have been noted in clinical trials and consideration to pancreatitis is needed. |
| Contraception: | Verify the pregnancy status of females of reproductive potential prior to initiating.  
Advise female patients of reproductive potential to use effective contraception during treatment with entrectinib and for at least 5 weeks following the final dose.  
Advise male patients with female partners of reproductive potential to use effective contraception during treatment with entrectinib and for 3 months following the final dose. |
| Renal impairment: | No dose adjustment is recommended for patients with mild or moderate renal impairment (CrCl 30 to < 90 mL/min calculated by Cockcroft-Gault equation). Entrectinib has not been studied in patients with severe renal impairment (CrCl < 30 mL/min). |
| Interactions: | Co-administration of entrectinib with a strong or moderate CYP3A inhibitor increases entrectinib plasma concentrations, which could increase the frequency or severity of adverse reactions.  
**Moderate & strong CYP3A inhibitors:**  
• Adults and paediatric patients >12 years with BSA>1.50 m²:  
Avoid co-administration of strong or moderate CYP3A inhibitors with entrectinib. If co-administration is unavoidable, reduce the entrectinib. |
- Paediatric patients 12 years and older with BSA $\leq 1.50 \text{ m}^2$:

Avoid co-administration of entrectinib with moderate or strong CYP3A inhibitors.

Avoid grapefruit products during treatment, as they contain inhibitors of CYP3A.

**Moderate and strong CYP3A inducers:**

Co-administration of entrectinib with a strong or moderate CYP3A inducer decreases entrectinib plasma concentrations which may reduce entrectinib efficacy. Avoid co-administration of strong and moderate CYP3A inducers with entrectinib.
Appendix 5  Example Genetic Reports

1. NTRK analysis report – no NTRK gene fusion detected

All Wales Molecular Genetics Laboratory

NTRK analysis

Conclusion: This patient has a reduced likelihood of response to treatment with TRK inhibitors.

Test results: No gene fusions involving NTRK1, 2 or 3 detected.

This NTRK1, NTRK2 and NTRK3 analysis of the tumour sample from this patient showed no evidence of a gene fusion involving NTRK1, 2 or 3.

Current evidence suggests that this patient would be unlikely to benefit from treatment with inhibitors targeting NTRK1, NTRK1, NTRK2 or NTRK3. The implication of this result for this patient must be discussed in the context of this patient’s disease status.

Patient-specific testing information: Targeted RNA sequencing which is consistent with a wildtype status of all NRKs.
2. NTRK analysis report – NTRK gene fusion detected

NTRK analysis

Analysed by:  

Dr. Dumi JONES

Checked by:  

A. Prodrick (MOEML Laboratory)  

Clinical Scientist  

Iain White  

Principal Clinical Scientist

Date: 07/10/20  

Version: 1.0  

Page: 35 of 37

Conclusion:

This patient may respond to TRK inhibitors.

Test results: TPM3-RET2 gene fusion detected; RHG35 rearrangement.

No gene fusions involving NTRK2 or NTRK3 detected.

The FISH-based NOC analysis of the tumour sample from this patient did not detect NTRK1 gene fusion. Analysis showed the evidence of a gene fusion involving the NTRK2 or NTRK3 genes.

It is possible that a tumour harbouring NTRK gene fusions exist in the patient, which has been shown to be resistant to NTRK inhibitors.

NTRK inhibitors are recommended for use as an option for treating NTRK fusion-negative solid tumours in adults and children if the disease is locally advanced or metastatic, or surgery is not possible due to health problems, and the patient has no other satisfactory treatment options [6]. The implication of this result for the patient should be determined in the context of the patient's full clinical details.

Please refer to specific testing information: NTRK1 mRNA was used for FISH and sequencing, providing an 85% sensitivity for rearrangement detection.
3. RNA-based NGS report (including NTRK gene fusion analysis where NTRK gene fusion is detected)

**Lung analysis**

Conclusions: This patient has a reduced likelihood of response to treatment with inhibitors specifically targeting ALK or ROS1.

Test results: **TMP3-REX1** gene fusion detected. IDH3B somatic/ref.

No gene fusions involving ALK, RET, ROS1, NTRK1 or NTRK3 detected. The EGFR**R759V** structural variant and V699R exon 19 skipping variant were NOT detected.

Test results for SLC14A1 hotspot variant analysis was reported separately.

**Histology:** Adenocarcinoma.

**Lung analysis**

**Test results:**

- **TMP3-REX1** gene fusion detected.
- **IDH3B** somatic/ref.

**Conclusion:**

This patient has a reduced likelihood of response to treatment with inhibitors specifically targeting ALK or ROS1.

**Test results:**

- **TMP3-REX1** gene fusion detected.
- **IDH3B** somatic/ref.

No gene fusions involving ALK, RET, ROS1, NTRK1 or NTRK3 detected.

The **EGFR R759V** structural variant and V699R exon 19 skipping variant were NOT detected.

Test results for SLC14A1 hotspot variant analysis was reported separately.

In patients with tumours harbouring an NTRK gene fusion, treatment with TKI inhibitors has been shown to be associated with high objective response rates (ORR).

TKI inhibitors are recommended for use as an option for treating NTRK fusion-positive solid tumours in adults and children. If the disease is locally advanced/metastatic, or surgery could cause severe health problems, and the patient has no satisfactory treatment options (e.g. chemotherapy), then TKI therapy is recommended as the first line treatment option. However, due to the paucity of data and the complexity of the disease, it is important to closely monitor patients for progression and adjust therapy according to clinical guidelines. A multidisciplinary team approach is recommended for the management of these patients.

**Patient-specific testing information:**

- **NGS:** RNA-Seq was used for RNA-cancer profiling, providing a 95% sensitivity for rearrangement detection.

---

**Date:** 07/10/20  
**Version:** 1.0  
**Page:** 36 of 37
4. RNA-based NGS not possible (insufficient quantity or quality of RNA)
